# The Problem

Onchain identity/reputation is essential to #DeFi

Onchain identity/reputation rapitation should be private

Onchain identity/reputation rapitation scoring methodology should be public

No onchain reputation standard

No way to agregate cross chain identity/reputation

# The Solution

We need a **universal reputation score with privacy in mind!**

We achieve this by:

- Creating a credit score called “FusionScore” based on multiple addresses and chains while keeping the account information private.
- Like real world credit scores (FICO score), the FusionScore enables financial products to model risk based on individual user’s risk profile, and it is a basic building block of any financial system.
- Fusion Credit leverages zero knowledge proof to hide all the account information, while ensuring the ownership of these accounts while not exposing the underlying account information.
- The exact process to create the FusionScore is public (built into the zero knowledge circuit), this allows the community to contribute and come up with a better methodology.
